

# Layered CAD/CSG Geometry for Neutronics Modeling of Advanced Reactors Elliott Biondo, Gregory Davidson, Brian Ade

Oak Ridge National Laboratory, 1 Bethel Valley Rd., Oak Ridge, TN, 37830

#### Shift Overview

- ORNL's flagship Monte Carlo (MC) radiation transport code
- Fission, fusion, and defense applications

#### Features

- Fixed-source and k-eigenvalue simulations
- Designed to scale from laptops to supercomputers with CPU and GPU execution
- Supports Shift CSG, "reactor aware" CSG, MCNP CSG, and DAGMC CAD geometry

ITER neutron flux

### CSG and CAD Geometries

- Constructive Solid Geometry (CSG)
- Primitive shapes combined using logic operations
- Generally linear or quadratic surfaces
- Tedious to create/combine

### Computer-Aided Design (CAD)

- Models converted into surface/volume meshes
- Support for higher order surfaces
- Higher RAM requirements

- Automatic coupling with the Denovo 3D  $S_N$  code to perform CADIS/FW-CADIS
- Advanced features such as non-uniform domain decomposition, inline depletion, and on-the-fly Doppler broadening

Dose rate, urban scenario

- Combine CSG/CAD for advanced reactor analysis:
- Use existing CAD models from thermal hydraulics or structural mechanics analysis
- Rigorously model complex components such as spacer grids or additively manufactured fuel elements

## Layered Geometries in Shift

- A *layered* geometry type has been implemented in Shift, allowing CSG and CAD geometries to be combined arbitrarily
- Constructed from *constituent models*, *objects*, and *layers*
- Tracking is done on all layers

1:	procedure FIND_ACTIVE_LAYER(pos)
2:	for layer_index $\in [\max\_layer\_index \dots 0]$
3:	for object $\in$ layers[layer_index].objects()
4:	$\mathbf{if}$ object.contains_point(pos)
5:	$cell \leftarrow object.find\_cell(pos)$
6:	<b>if not</b> cell.material.is_transparent()
7:	return layer_index
8:	end if
9:	end if
10:	end for
11:	end for
12:	end procedure

independently, with cross sections and tallies evaluated only on the *active* layer

- Standard MC tracking algorithm left intact, with layered geometry modifications to the following routines:
- distance\_to\_boundary
- move\_across\_surface
- move\_within\_cell

1: <b>procedure</b> DISTANCE_TO_BOUNDARY(pos, dir)			
2:	$min_dist = distance_to_outer_boundary(pos, dir)$		
3:	for layer $\in$ layers		
4:	$current_obj = layer.find_object(pos)$		
5:	if current_obj is not null		
6:	$obj_dist \leftarrow current_obj_distance_to_boundary(pos, dist)$		
7:	$\min_{dist} = \min(\min_{dist}, obj_{dist})$		
8:	else		
9:	for $obj \in layer.objects()$		
10:	$bbox_dist = distance_to_box(obj.bounding_box, pos, dir)$		
11:	$\min_{dist} \leftarrow \min(\min_{dist}, bbox_{dist})$		
12:	end for		
13:	end if		
14:	end for		
15:	return $\min_{-dist}$		
16: <b>ei</b>	16: end procedure		

#### Transformational Challenge Reactor (TCR) Demonstration Problem

SiC reflector

• Cold zero power simulation with 25 inactive cycles and 25 active cycles, with  $5 \times 10^6$ 

- 1.00 <del>ک</del>

12.45

12.35 g

12.25

 Conceptual reactor design with a core consisting of additively manufactured cogshaped fuel elements

• Fuel elements were designed in CAD and contain higher order surfaces not easily represented in CSG

histories per cycle on 960 CPU cores

• Flux, fission source, and  $k_{eff}$ results matched expectations
